- 05 Review of Literature**
- 06 System Design and Progress**

Background of The Study

In aquaculture, especially shrimp ponds, we need to pay attention to the environment where the cultivation is in order to obtain maximum result. Water quality is one of the most important things to pay attention to. In fact, the most important factor in water quality is the oxygen content, which affects the pH value. Often this level is influenced by aquatic bio-organisms, especially algae. Algae monitoring can be done by looking at the color of the water. This is where the idea for the study of water quality came from. It is hoped that this tool will be able to monitor algae as in a lab test

Purpose

- Creating a tool to record data on samples
- Create a prediction system based on recorded data

Problem formulation

- How to create device for data sensing and collecting
- How to make good model for predict the sample

Scope and Limitation

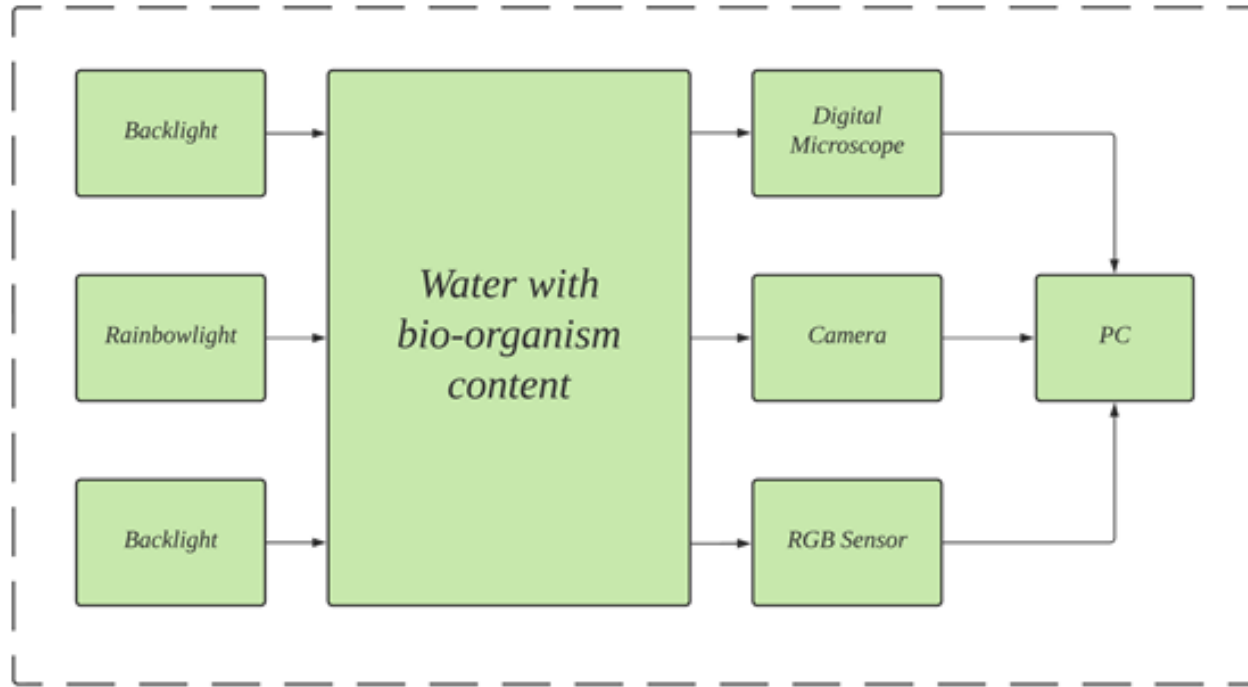

- Sample is conditioned data whose concentration level is known.
- Model is created from the data recorded from the device

Literature review

Mean Error				5.14

Conclusion

- Prototype is already be used for monitoring and retrieving data
- The data obtained from food colorant have appropriate values between the concentration and the graphic form of the single red and green colorant. Meanwhile, for the blue colorant and the mixed colorant, the data obtained is still not in accordance with the graphic form, which has a difference with the number of concentration settings.
- The first model with a simple layer architecture and using normalization has better predictive results than the model with a complex layer architecture with an error value of 3.78 compared to 5.14.

Thankyou
